## **Image Segmentation**

LATEST SUBMISSION GRADE

Ö	5.88%	
1.	At the heart of image segmentation with neural networks is an encoder/decoder architecture. What functionalities do they perform?	1/1 point
	The decoder extracts features from an image and the encoder takes those extracted features, and assigns class label to the entire image.	
	The decoder extracts features from an image and the encoder takes those extracted features, and assigns class labels to each pixel of the image.	
	The encoder extracts features from an image and the decoder takes those extracted features, and assigns class labels to each pixel of the image.	
	✓ Correct Correct!	
	The encoder extracts features from an image and the decoder takes those extracted features, and assigns class label to the entire image.	
2.	Is the following statement true regarding SegNet, UNet and Fully Convolutional Neural Networks (FCNNs):	1 / 1 point
	Unlike the similarity between the architecture design of SegNet & UNet, FCNNs do not have a symmetric architecture design.	
	True     False	
	✓ Correct Correct!	
3.	What architectural difference does the <i>number</i> represent in the names of FCN-32, FCN-16, FCN-8?	1/1 point
	The <i>number</i> represents the total number of pooling layers used in the architecture to help make predictions.	
	<ul> <li>The number represents the total number of filters used in the final pooling layer in the architecture to make predictions.</li> </ul>	
	<ul> <li>The number represents the total number of convolutional layers used in the final pooling layer in the architecture to make predictions.</li> </ul>	
	The number represents the factor by which the final pooling layer in the architecture up-samples the image to make predictions.	
	✓ Correct Correct!	
4.	Take a look at the following code and select the type of scaling that will be performed	1/1 point
	<pre>x = UpSampling2D(     size=(2, 2),</pre>	
	<pre>data_format=None, interpolation='bilinear')(x)</pre>	
	The upsampling of the image will be done by copying the value from the closest pixels.	
	The upsampling of the image will be done by means of linear interpolation from the closest pixel values	
	✓ Correct Correct!	

5. What does the following code do?

```
Conv2DTranspose(
                     filters=32,
                     kernel_size=(3, 3)
   It takes pixel values in the image, in a 3x3 array, and using the specified filters, creates a transpose of that array.

    It takes the pixel values and filters and tries to reverse the convolution process to return back a 3x3 array which

       could have been the original array of the image.
      ✓ Correct
          Correct!
6. The following is the code for the last layer of a FCN-8 decoder. What key change is required if we want this to be the last 1/1 point
   laver of a FCN-16 decoder ?
     def fcn8_decoder(convs, n_classes):
        o = tf.keras.layers.Conv2DTranspose(n_classes , kernel_size=(8,8),
                                                             strides=(8,8))(o)
        o = (tf.keras.layers.Activation('softmax'))(o)
        return o
   ○ n_classes=16
   strides=(16, 16)
   Using sigmoid instead of softmax.
   kernel_size=(16, 16)
      ✓ Correct
          Correct!
7. Which of the following is true about Intersection Over Union (IoU) and Dice Score, when it comes to evaluating image
                                                                                                               1 / 1 point
   segmentation? (Choose all that apply.)
   For IoU the numerator is the area of overlap for both the labels, predicted and ground truth, whereas for Dice Score
       the numerator is 2 times that.
      ✓ Correct
          Correct!
   Both have a range between 0 and 1
      ✓ Correct
          Correct!
   For both, IoU & Dice Score the denominator is the total area of both the labels, predicted and ground truth
   Unlike IoU, for Dice Score the closer the value is to 0 the closer the prediction is to the ground truth.
8. Consider the following code for building the encoder blocks for a U-Net. What should this function return?
                                                                                                               1 / 1 point
```

def unet\_encoder\_block(inputs, n\_filters, pool\_size, dropout): blocks = conv2d\_block(inputs, n\_filters=n\_filters) after\_pooling = tf.keras.layers.MaxPooling2D(pool\_size)(blocks) after\_dropout = tf.keras.layers.Dropout(dropout)(after\_pooling)

∪ blocks
○ after_dropout
after_dropout, after_pooling (you need to return after_pooling to be used in skip connections)
blocks, after_dropout
✓ Correct Correct!

9. For U-Net, on the *decoder* side you combine *skip connections* which come from the corresponding level of the *encoder*. Consider the following code and provide the missing line required to account for those skip connections with the upsampling.

(Important Notes: Use TensorFlow as tf, Keras as keras. And be mindful of python spacing convention, i.e (x, y) not (x,y))

```
lef decoder_block(inputs, conv_output, n_filters, kernel_size, strides, dropout):
    upsampling_layer = tf.keras.layers.Conv2DTranspose(n_filters, kernel_size, strides = strides,
    padding = 'same')(inputs)
 skip_connection_layer = # your code here
skip_connection_layer = tf.keras.layers.Dropout(dropout)(skip_connection_layer)
skip_connection_layer = conv2d_block(skip_connection_layer, n_filters, kernel_size=3)
 return skip_connection_layer
```

 $skip\_connection\_layer=tf.keras.concatenate([upsampling\_layer, conv\_output])$ 

Incorrect

 $Hint: the \ activation \ from \ the \ encoder \ at \ the \ same \ level \ as \ upsampling \underline{layer} \ is \ passed \ into \ the \ decoder\underline{block}$ function as a parameter.
